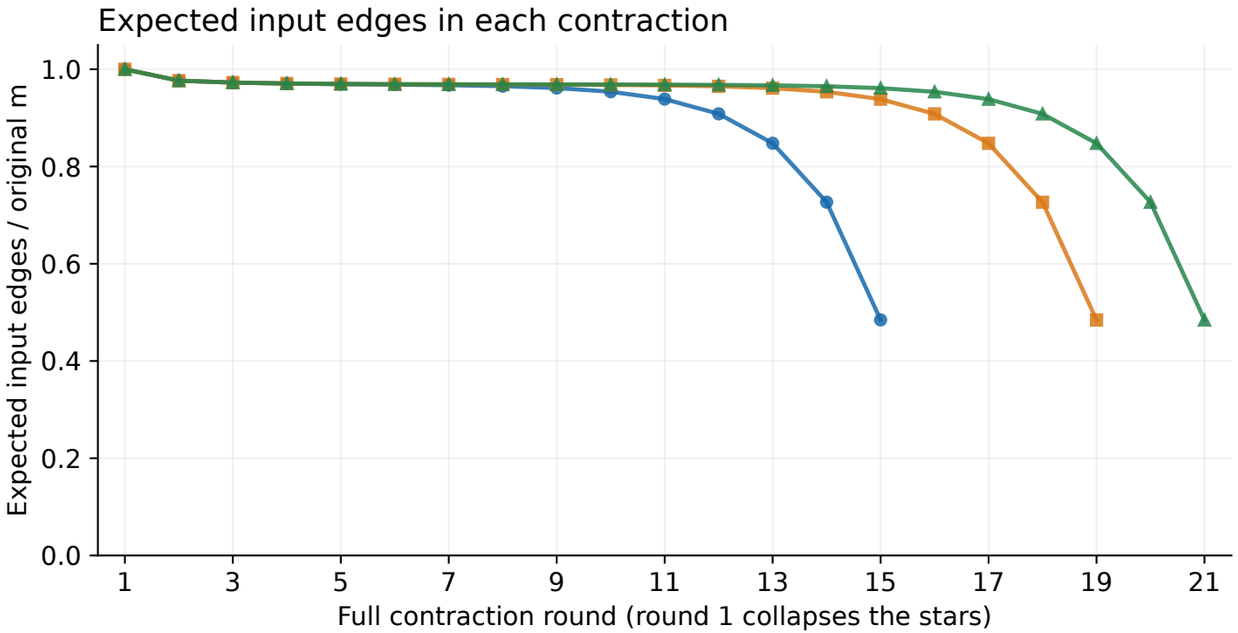
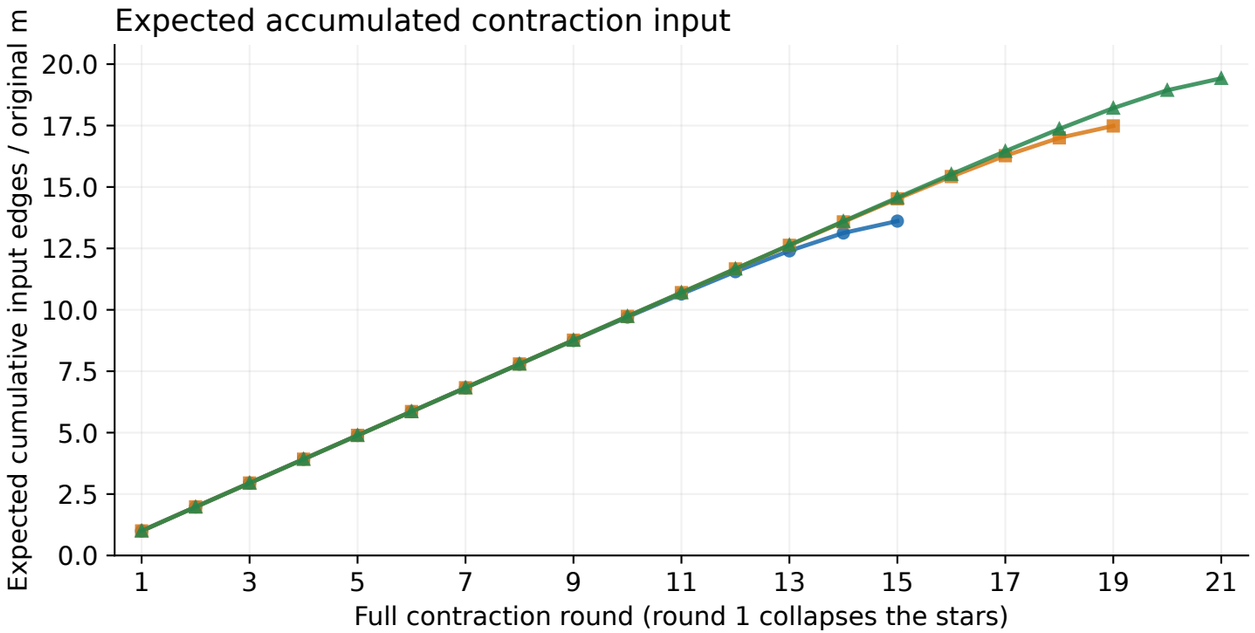
# THEORETICAL EXPECTATION · hierarchy-ordered leaf cores
## Uniform nonpath chords; m/n = 32; no measured timing or work data





n = 65,536 (15 full rounds)  n = 1,048,576 (19 full rounds)  n = 4,194,304 (21 full rounds)

Round 1 reads m edges. Core-round inputs use aligned blocks b = 1, 2, 4, ..., q/2; the final contraction leaves an empty quotient.
Markers include every defined input round; lines only connect that discrete expectation. Curves stop at their own final contraction.
These are ensemble expectations of one input-edge count per call, not measured scans, CPU work, memory or runtime predictions.
