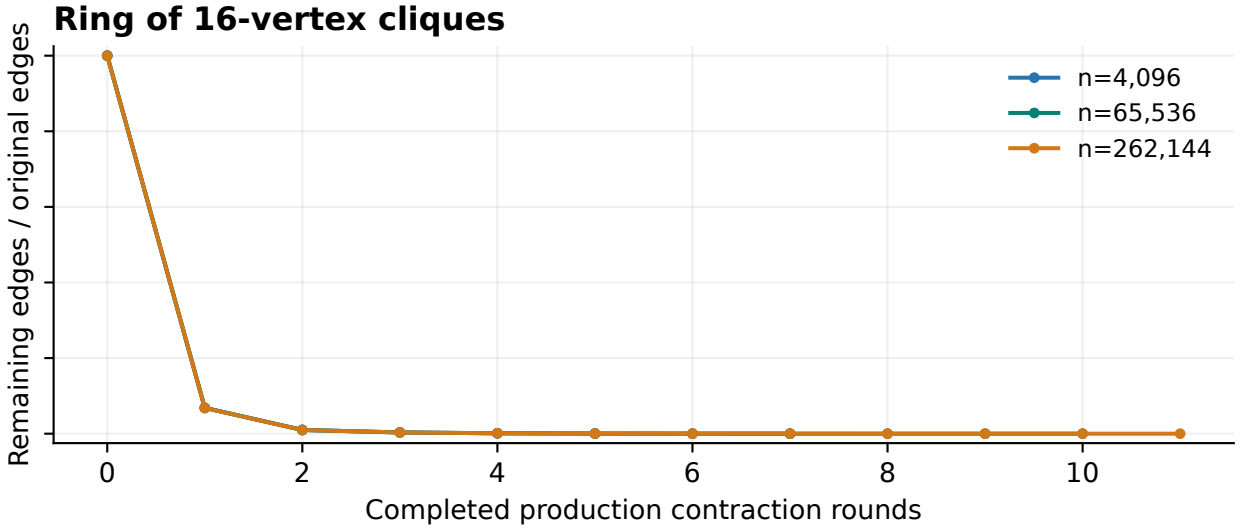
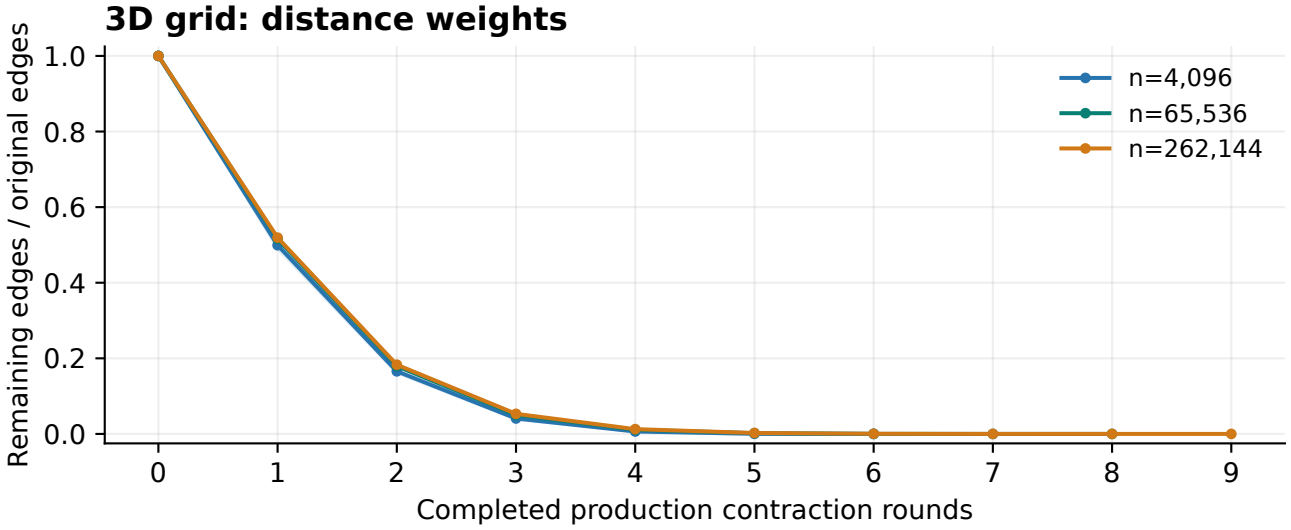
How quickly does plain compacting contraction discard edges?

Bipartite: 16-vertex side

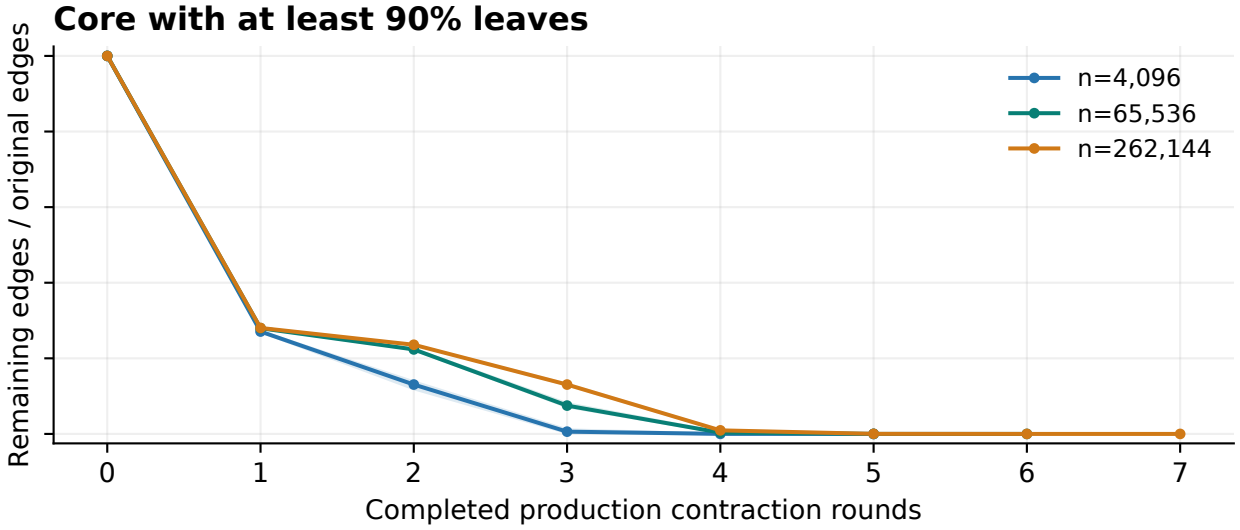
Ring of 16-vertex cliques



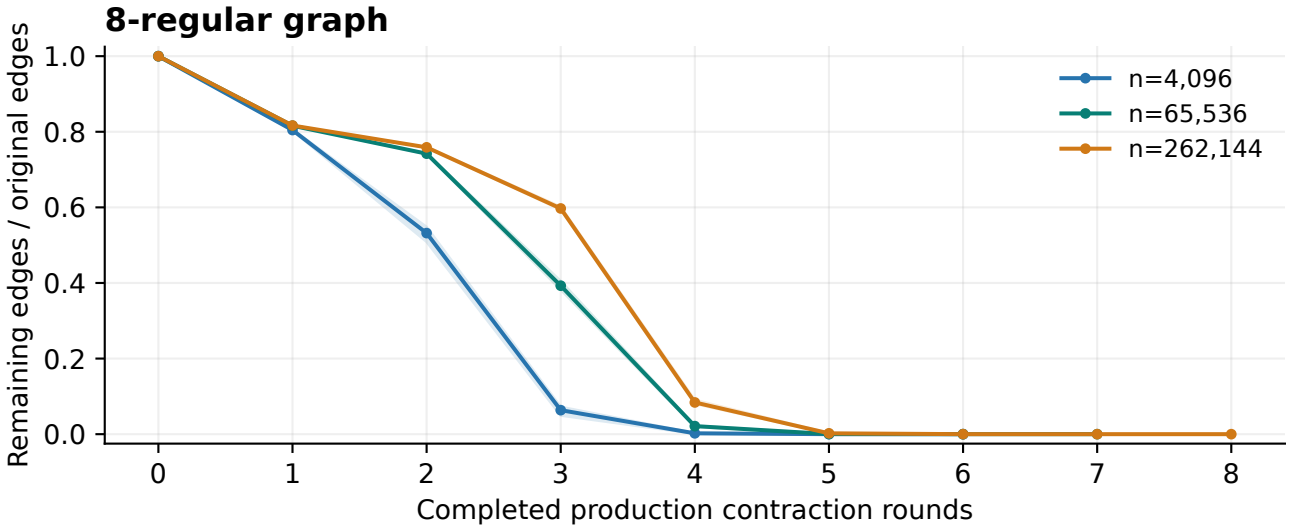
3D grid: distance weights



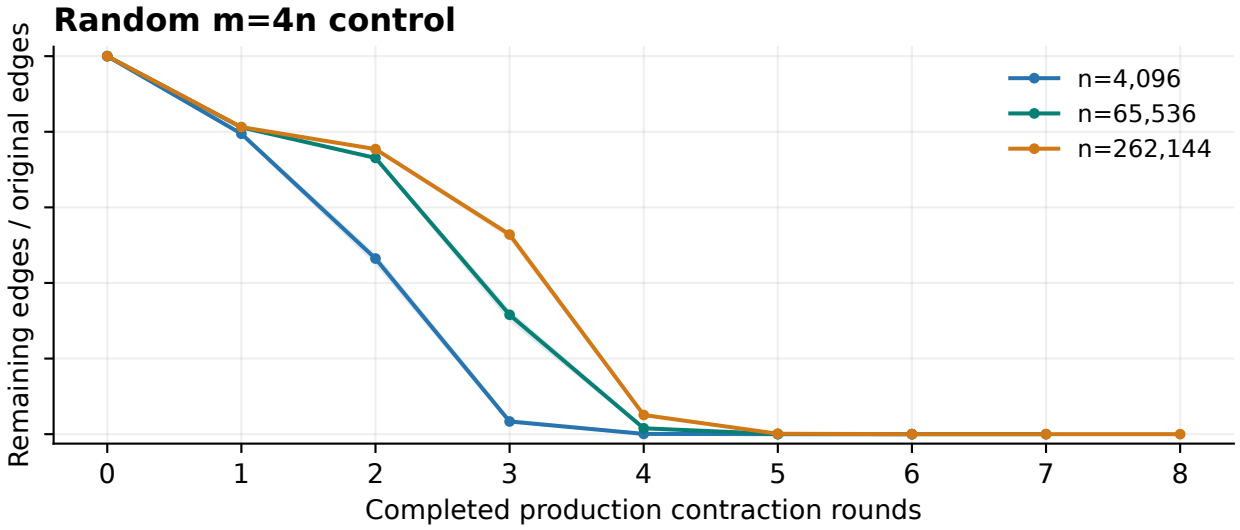
Core with at least 90% leaves



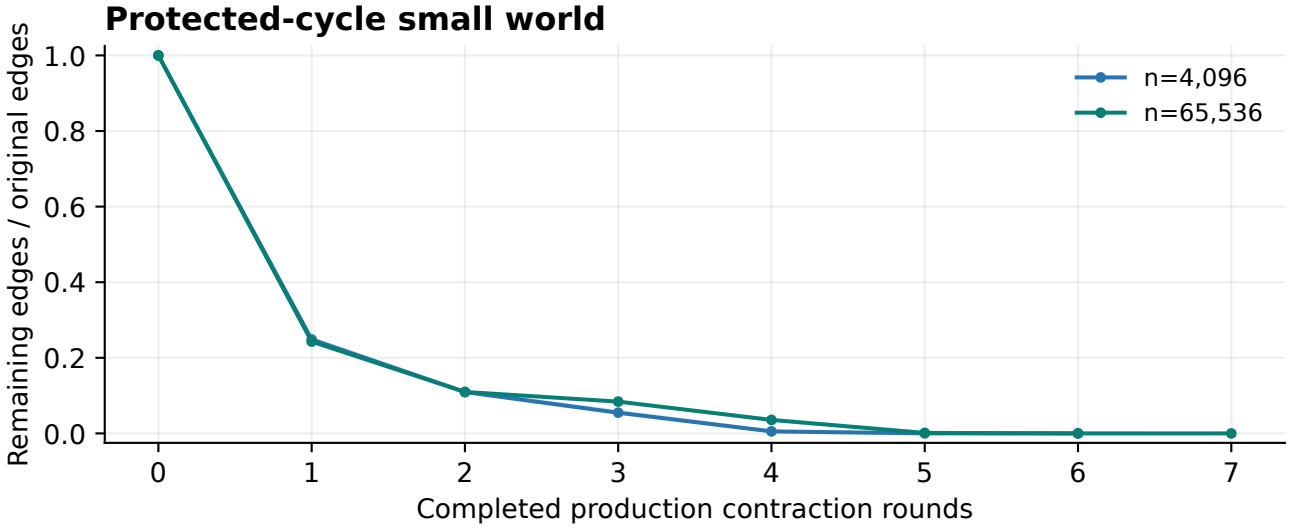
8-regular graph



Random m=4n control



Protected-cycle small world



Untimed traces: one per graph.
Means and ranges over 3 graph seeds.
Terminated traces remain at zero.
No sampling-seed replication.

This is repeated compacting Borůvka,
not KKT's recursive subproblem volume.
